

VACCINE AGAINST LIPOPOLYSACCHARIDE CORE

INSAI

Cross-reference to related application

This application is a conversion of our prior U.S.
5 provisional application, U.S. 60/046,680, filed May 16,
1997, which is hereby incorporated by reference.

Field of the Invention

This invention is in the general field of reducing
the adverse effects of endotoxin from Gram-negative
10 bacteria.

Background of the Invention

Endotoxin (also called lipopolysaccharide [LPS])
is thought to exert many of its toxic effects following
its entry into the bloodstream. The presence of
15 endotoxin in the blood, endotoxemia, can occur in various
situations, e.g., during periods of stress. For example,
endotoxemia can occur in patients undergoing certain
types of surgery, anti-cancer chemotherapy, radiation
therapy, and immunosuppressive treatment, and it can also
20 occur in patients suffering from various trauma, burns,
or wounds. It occurs as well in military, police, and
fire-fighting personnel as well as in endurance athletes,
horses, and in livestock. It can also occur after
immunosuppressive treatment, and in patients with sepsis
25 or septic shock as well as in those suffering from stress
or trauma as discussed above.

One way that endotoxin may reach the blood is from
the patient's intestine because the intestine loses its
ability to contain LPS during periods of infection,
30 stress, or trauma. Normally, intestinal flora contain a
large amount of endotoxin from Gram-negative
microorganisms. It is estimated that the average human
colon contains 25 billion nanograms of endotoxin, which
is an enormous quantity when one considers that endotoxin
35 concentrations on the order of 10^2 are toxic to humans.

005240" 94522460

- 2 -

09403545-042500

The leakage of live bacterial cells into the bloodstream can result in infection as the bacteria multiply. Many of the bacteria in the intestine are dead, and endotoxin contained within cell membrane fragments of dead bacteria can also enter the bloodstream. In this case infection per se does not develop. Instead, endotoxin from dead bacteria in the blood is thought to initiate a systemic inflammatory response by activating macrophages which release tumor necrosis factor and various interleukins. Endotoxin exposure and the resulting systemic inflammatory response can cause damage to body organs, including the lungs, kidneys, heart, blood vessels, gastrointestinal tract, blood/coagulation system, and nervous system. This proinflammatory response can be severe, causing organs to fail, sometimes resulting in death.

LPS is thought to be a major causative agent of septic shock. It is increasingly recognized that less severe forms of this systemic inflammation cause organ dysfunction as opposed to organ failure. In its mildest form, endotoxemia can cause fever, nausea, and malaise, common symptoms of patients following surgery or patients who are hospitalized for other reasons, and the symptoms even occur, for example in athletes following strenuous activity.

Greater exposure of the host to endotoxin or a greater susceptibility to its effects can result in a larger inflammatory response. For example, many post surgical patients develop pulmonary dysfunction requiring supplemental oxygen. They may also develop hematologic or renal complications. These complications often do not lead to death but instead cause suffering and increase hospital length of stay and thus health care costs. It is estimated that at least 10% of the 28 million United States surgical patients may develop systemic

- 3 -

inflammation and possible complications as a result of exposure to endotoxin from Gram-negative microorganisms. See generally, Bennett-Guerrero et al., Crit Care Med, 25:A112, 1997 and Bennett-Guerrero et al., J. Am. Med. Ass. 277:646-650, 1997 discussing certain types of surgical patients at risk.

Among the bacteria and their respective endotoxins which are thought to commonly cause complications are *Escherichia coli*, *Klebsiella pneumoniae*, *Pseudomonas* 10 *aeruginosa*, *Proteus spp.*, *Enterobacter spp.*, *Salmonella spp.*, *Serratia spp.*, and *Shigella spp.* These bacteria are Gram-negative bacteria, a class characterized by a specific type of outer membrane which comprises a lipopolysaccharide (LPS) as a major constituent.

15 Although the LPS constituent varies from one bacterial species to another, it may be generally described with reference to Fig. 1 as consisting of three structural regions: a) Lipid A; b) core; and c) O-polysaccharide outer region. The lipid region of Lipid A is embedded in 20 the outer leaflet of the outer membrane. The oligosaccharide core region is positioned between Lipid A and the O-polysaccharide outer region. Lipid A has the same basic structure in practically all gram negative bacteria and is the main endotoxic determinant. The LPS 25 core region shows a high degree of similarity among bacterial genera. It usually consists of a limited number of sugars. For example, the inner core region is constituted of heptose and 3-deoxy-D-manno-2-octulosonate (KDO) residues, while the outer core region comprises 30 galactose, glucose, or N-acetyl-D-glucosamine residues displayed in various manners depending upon the strain. The O-polysaccharide outer region (also called O-specific antigen or O-specific side chain) is highly variable and is composed of one or more oligosaccharide repeating 35 units characteristic of the serotype.

005240" 9452460

- 4 -

The presence of the O-polysaccharide side chain confers a smooth aspect to a culture of a wild type bacterium, and, for this reason, wild type bacteria with polysaccharide side chain are usually referred to as smooth bacteria in contrast with mutant cultures which show a rough aspect because they lack the O-polysaccharide side chain and (in some cases) part of the core region. For example, the different chemotypes of rough mutants from Salmonella are conventionally designated by the terms Ra, Rb, Rc, Rd, and Re.

As seen from Fig. 2, the LPS of each type comprises the lipid A structure. The Ra chemotype is characterized by a complete core region, the Rb chemotype is characterized by the absence of N-acetyl-D-glucosamine residues, the Rc chemotype is characterized by the absence of N-acetyl-D-glucosamine and galactose residues, the Rd chemotype is characterized by the absence of any residues constituting the outer core, and the Re chemotype is characterized by the sole KDO region attached to lipid A.

Fig. 3 is a diagrammatic representation of the five known complete core chemotypes of *E. coli* as well as the one known complete core chemotype of all *Salmonella* species.

Not all LPS molecules on the surface of a given cell or in a homogeneous population of cells have the same number of oligosaccharide side chains. For example, a single cell from a population of smooth strain bacteria may include some rough forms of LPS, i.e., LPS that is not substituted with any polysaccharide side chains.

Various treatments for the toxic effect of LPS have been proposed or tried. One of a mammal's defenses against endotoxemia is the presence of antibodies in the blood which can bind to and neutralize blood borne endotoxin, and immunologic methods have been proposed as

005240" 9452460

- 5 -

an alternative or additional treatment to antibiotic therapy to prevent or control such infections or to reduce the toxic effect of endotoxin. For example, conventional polyclonal antisera and hyperimmune sera have been used in an attempt to bolster the native defenses of patients against the adverse effects of bacteria, presumably by enhancing opsonization and phagocytosis of the bacterial cells or by neutralization of the biological activity of LPS. However, the effectiveness of the antisera varies greatly depending upon a large number of factors including, for example, the composition and titer of the specific antibodies, which cannot be easily standardized. The use of these antisera may also carry a risk of transmission of viral infectious diseases.

Patients or potential donors of hyperimmune sera have been vaccinated (i.e. actively immunized) with various immunogens in an attempt to stimulate the host synthesis of cross-reactive anti-endotoxin antibodies. Various vaccine compositions and methods of immunization have been studied over the last two decades. See, e.g., Bhattacharjee A, WO 95/29662; McCabe WR, J Infec Dis 1988; 158:291; Greisman SE, Proc Soc Exp Bio Med 1978; 158:482; Goto M, Res Comm Chem Path Pharm 1992; 76:249; DeMaria A, J Infec Dis 1988; 158:301; Baumgartner JD, J Infec Dis 1991; 163:769; Cross A, J Infec Dis 1994; 170:834; Cryz SJ, US 4,755,381; Miler JM, J Med Microbiol 1977; 10:19; Ashton, FE, Microb Pathog 1989; 6:455; Dorner F, US 4,946,677; Cryz SJ, US 4,771,127; Collins MS, US 4,693,891; Pier GB, US 4,285,936; Cryz SJ, J Infec Dis 1991; 163:1040; Cryz SJ, J Clin Invest 1987; 80:51; PCT WO92/06709; US 5,641,492.

Vaccines should avoid the common side effects -- fever, malaise, and other forms of toxicity -- in the animals and humans receiving them, as reported, for

005240" 9452460

- 6 -

example, in (Ziegler et al., New Eng. J. Med., 307:1225 (1982); DeMaria, Infec. Dis. 158:301 (1988). These side effects may be exacerbated in high risk individuals, such as pre-surgical elderly and sick patients with multiple
5 medical problems, an important target population for the vaccine.

A study has been published in which the concentration of anti-endotoxin-core antibodies was measured in 301 patients prior to cardiac surgery and the
10 relationship to postoperative outcome tested. Bennett-Guerrero et al. J. Am. Med. Ass. 277:646 (1997). These anti-endotoxin-core antibodies were measured using an ELISA which allegedly detects antibodies to the core of LPS. This study found that patients with a higher level
15 of core-specific antibodies were less likely to die or have a prolonged hospital length of stay associated with complications potentially attributable to endotoxemia. This publication did not describe a method for controlling or treating endotoxemia in these patients.

20 Regarding the toxicity of LPS, there is some evidence that the toxicity of certain types of lipid A or LPS can be reduced in several ways.

Liposomes have been suggested as carriers for lipid A containing agents. For example, incorporation of
25 LPS into liposomes was shown to reduce the toxicity of LPS from *Neisseria meningitidis* in an attempt to create a vaccine specific for *N. meningitidis* LPS. Petrov et al., Infect. Immunity 60:3897 (1992). Other prior art showed that the incorporation of a chemically altered form of
30 lipid A called monophosphoryl lipid A (MPLA) into liposomes resulted in reduced toxicity of the MPLA component. Richards et al. Vaccine 7:506 (1989). It appeared as if incorporating the MPLA and malaria immunogen into the liposomes resulted in an adjuvant
35 effect, that is, incorporation into liposomes increased

005210 942546 042500

- 7 -

the immunogenicity of the malaria immunogen component of this anti-malaria vaccine.

Methods to detoxify the lipid A component of LPS have also been previously described. Bhattacharjee et al. J. Infec. Dis. 173:1157 (1996).

Genetic alteration of bacterial strains has been reported in which the resulting bacteria contain a LPS whose lipid A component causes less biological toxicity. Somerville et al., J. Clin. Invest. 97:359 (1996).

10 Summary of the Invention

Vaccination (active immunization) with complete core rough LPS antigen particularly from *E. coli* K12 provides both strain-specific protection and cross-core protection without unacceptable toxicity or other side effects. An antigen is considered a complete-core, rough LPS in that it includes, at a minimum, Lipid A, heptose and 3-deoxy-D-manno-2-octulosonate (KDO) residues, as well as the outer core galactose and glucose residues. Typically, it also includes the outer core N-acetyl-D-glucosamine residues. For example, it includes the outer core structure of Rb and typically also the structure of Ra, as shown in Fig. 2. It does not include the O-polysaccharide outer region (also called O-polysaccharide side chain).

25 Thus, one aspect of the invention generally features a method of reducing the adverse effects of endotoxemia in a warm-blooded animal (a mammal, typically a human patient), by administering an effective amount of a composition comprising complete-core, rough, lipopolysaccharide (LPS) antigen (e.g., an Ra LPS) of a Gram-negative bacterium, particularly *E. coli* K12. Preferably, the immunizing composition is a cocktail of complete-core, rough, lipopolysaccharide (LPS) antigen from other Gram-negative bacterium. Useful rough LPSs

00540" 9452460

- 8 -

are those from *E. coli* and *Salmonella*, particularly from each of the five known chemotypes of *E. coli*: *E. coli* R1, *E. coli* R2, *E. coli* R3, *E. coli* R4, and *E. coli* K12 (Jansson et al., *Eur. J. Biochem.* 115:571 (1981)). See

5 Fig. 3. Only one core structure accounts for all known *Salmonella* species, and any Ra *Salmonella* strain can be used, for example *Salmonella minnesota* R60. Rietschel et al. *Infect. Dis. Clin. N. Am.* 5:753 (1991). Complete core LPS lacking polysaccharide side chains from other

10 Gram-negative bacteria that may be useful include those from the family Enterobacteriaceae (i.e. the genera *Escherichia*, *Salmonella*, *Klebsiella*, *Citrobacter*, *Shigella*, *Proteus*, *Edwardsiella*, *Enterobacter*, *Hafnia*, *Serratia*, *Providencia*, *Morganella*, *Yersinia*, *Erwinia*),

15 the family Pseudomonadaceae, e.g., *Pseudomonas aeruginosa* and the family Bacteroides, e.g., *B. fragilis*. See, generally, *ESSENTIALS OF MEDICAL MICROBIOLOGY*, 3rd Ed., Volk, et al., pp. 397 and 416 (J/P. Lippencott Co. Philadelphia, PA (1986) for a compilation of Gram-

20 negative bacteria. The composition may include a complete-core, rough, LPS antigen from several (two, three, four or more) Gram-negative bacteria, each of which is different (e.g., different species or at least different strains of the same species) from the other.

25 In such mixtures, the core antigen from each of the four bacteria may be present in functionally equal amounts (e.g., in amounts which are intended to maximize the expression of the common core epitope(s)).

Desirably, vaccines should cause the patient to

30 produce an antibody that binds to an epitope in the core region of the LPS core of at least one Gram-negative bacterial strain whose LPS is not part of the composition, thereby providing for cross-reactivity and cross-protection. It is difficult to achieve genuine

35 vertical and genuine horizontal cross-reactivity and

- 9 -

cross-protection against smooth and rough gram negative LPS, in particular in *E. coli*, the species most commonly isolated from surgical and intensive care unit patients. Cross-reactivity is of two kinds, which may be described
5 as horizontal and vertical. Vertical cross-reactivity refers to an antibody's reaction with LPS's within the same strain that are different sizes, i.e., having different degrees of substitution or length of the O-specific side chain. Horizontal cross-reactivity refers
10 to an antibody's reaction with core structures that are different -- i.e., different strains, species, etc. In particular, the patient's antibody response desirably will bind and protect against smooth as well as rough forms of LPS. Without wishing to bind ourselves to any
15 particular theory, we believe that the epitope of the immunogen used in the vaccine according to the invention is accessible in both smooth and rough forms of LPS.

It may be particularly useful to include the antigen in a liposome structure. For example, the ratio
20 (weight:weight) of lipid in the liposome to the LPS antigen is between 1:1 and 5000:1 (more typically between 10:1 and 1000:1). The liposome may include a component to provide stability or alter the compound's charge, selected from the group consisting of: phospholipid,
25 cholesterol, positively charged compounds, negatively charged compounds, amphipathic compounds. Multilamellar type liposomes (MLV) in particular may be used. Small or large unilamellar liposomes (SUVs and LUVs) also may be used.

30 The composition may be administered intramuscularly intravenously, subcutaneously, intraperitoneally, via the respiratory tract, or via gastrointestinal tract. The dose of antigen can be readily determined by standard dosage trials which
35 correlate dosage with titre and/or protection. A

005240 " 945246 04500

- 10 -

functional dosage may be between 0.01 ng and 1000 ng per kilogram of patient body weight, but further optimization may indicate that higher dosages (up to 100 μ g/kg of body weight) are desirable consistent with safety and avoiding untoward side effects. IgM antibodies can provide suitable protection, and, were the goal is generation of IgM antibodies, the composition may be administered sufficiently in advance to permit IgM antibodies to be produced (at least 2 days more typically longer) prior to potential endotoxin exposure. Also in that case, the composition would not be administered so far in advance that the IgM response deteriorates substantially -- e.g., less than 14 days prior to exposure. The composition may be administered in multiple doses, the first of which is administered at least 2 days prior to potential endotoxin exposure.

Antigen in the composition may be present as part of bacteria that have been killed e.g., by heat or formaldehyde. Alternatively, the antigen may be separated from the bacterium before formulation of the composition. Alternatively the LPS antigen can be in the form of purified LPS or complexed to an acceptable carrier. Appelmelk et al., J. Immunol. Meth., 82:199 (1985).

The antigen may be chemically detoxified. The bacterium may be genetically engineered for various reasons, e.g., to reduce toxicity. The composition may also include an adjuvant, e.g., alum.

The invention also features vaccine compositions described above in connection with the method. Thus, the vaccine is comprised of an effective amount of one or more complete-core, rough, LPS of a Gram negative bacteria. Upon administration to a warm-blooded animal the compositions stimulate the synthesis of antibodies which recognize an epitope in the core region of the LPS molecule and which are cross-protective against

- 11 -

endotoxemia caused by at least two different Gram-negative bacterial strains having different core structures. In particular, the antibodies synthesized in response to the vaccine are cross-protective against

5 smooth LPS as well as complete core rough LPS (lacking O-polysaccharide side chains). In E. coli, the antibodies induced by the vaccine preferably react with all common smooth strain isolates, and preferably also with rough forms of all five core types (R1, R2, R3, R4, and K12).

10 Preferably the antibodies induced by the vaccine are also reactive with both smooth and rough forms of LPS of different strains of Salmonella.

Furthermore, the vaccine described in this invention preferably causes no unacceptable toxicity

15 following its administration to mammals. Toxicity may be controlled by incorporating the LPS into liposomes, by detoxifying the LPSs lipid A component and/or by alteration of the lipid A component by genetic manipulation of the above mentioned bacterial strains.

20 The vaccine composition can be used to immunize a donor, from whom antibodies are harvested for administration to a patient. Preferably the antibodies harvested comprise a substantial percentage of IgM class antibody.

25 Another aspect of the invention features a method of quantitating lipopolysaccharide incorporated into liposomes (PAS method). This method, unlike e.g., typical radiolabelling methods, does not require conversion of the lipopolysaccharide to a form which is unsuitable for

30 clinical use.

Other features and embodiments of the invention will be apparent from the following description of specific embodiments.

Brief Description of the Drawings

Fig. 1 is a diagrammatic representation of smooth and rough LPS.

Fig. 2 is a diagrammatic representation of the chemical structure of Salmonella R-mutants.

Fig. 3 is a diagrammatic representation of the chemical structure of known core types found in Salmonella and Escherichia complete core rough LPS.

Description of the Preferred Embodiments10 Medical Indications

The patients to be treated with the vaccine include those at risk for endotoxin exposure. Specific candidates for active immunization include patients scheduled for surgery, patients subjected to chemotherapy or radiation therapy as well as burn patients, trauma patients, dialysis patients and hospitalized (particularly ICU) patients, whether or not they exhibit sepsis or septic shock. Other potential candidates for vaccination include members of the military, fireman, and policeman, as well as endurance athletes and livestock such as horses or cows.

LPS Component

As described above, the LPS antigen to be included in the vaccine can be any complete core LPS lacking O-polysaccharide side chains, preferably from *E. coli* K12, as described below. Although Rb chemotypes may be used, the preferred embodiment is Ra or complete core chemotypes. LPS can be purified from cultured bacteria or purchased commercially, e.g., from Difco, Sigma, List Biologicals, in Campbell, California. The organisms in question are widely available from depositories, including the National Culture Type Collection in England (NCTC); the University of Edinburgh collection in

005240" 945246

- 13 -

Edinburgh Scotland,¹ and the Forschungsinstitut in Borstell (FB), Germany D-2061. Examples of specific bacterial include, but are not limited to, the following strains: E. coli K12 -- e.g., Edinburgh #MPRL2320; FB
5 W3100 or List Biologicals; E. coli R1 -- e.g. Edinburgh #MPRL2316 or FB F470; E. coli R2 -- e.g., Edinburgh #MPRL2317 or FB F576; E. coli R3 -- e.g., Edinburgh #MPRL2318 or FB F653; E. coli R4 -- e.g., Edinburgh #MPRL2431 or FB F2513; Ra S. minnesota R60 Edinburgh
10 #MPRL1265 or List Biologicals; S. typhimurium Ra (e.g. TV119,1542), P. aeruginosa PAC611 (e.g, Edinburgh #MPRL1091) and K. aerogenes M10B (e.g, Edinburgh #MPRL0954), S. minnesota Rb chemotype (e.g. Edinburgh #MPRL1091) R345); Bacteroides fragilis -- NCTC 9343; B.
15 vulgatis NCTC 10583; B. thetaiotaomicron NCTC 10582.

Without wishing to bind ourselves to a single theory by which the invention operates, we note that the inner core region may contain an important epitope in terms of stimulating the synthesis of cross-reactive and
20 cross-protective anti-LPS antibodies. However, sufficient outer core structures may be necessary to maintain the inner core epitope in a three-dimensional structure which is similar to that encountered in clinically significant LPS isolates (i.e. smooth and
25 rough forms of complete core LPS). The absence of polysaccharide side chain (i.e. rough LPS) allows the core epitope to be the dominant epitope. In smooth forms of LPS, the polysaccharide side chain is a much more dominant epitope than the core thus significantly
30 reducing the relative amount of anti-core antibody produced. In other words, vaccines containing smooth LPS elicit primarily a serotype specific (i.e. anti-polysaccharide side chain) antibody response as opposed

¹ University of Edinburgh Medical School (Edinburgh, Scotland), attention Ian Poxton, Ph.D.

005240" 9452460

- 14 -

to the anti-core response which is the focus of our invention.

E. coli K12 may be particularly useful because it is not generally present in the patient population.

- 5 Therefore, K12 is less likely to provoke a memory response to the outer core, and more likely to provoke a cross-reactive memory response to the inner core.

If whole bacteria are to be included in the vaccine the bacterium will be killed by a technique well
10 known to those in the art, such as heat killing or formaldehyde killing. In this case, the entire LPS of rough mutant bacterium will be included as part of the killed bacterium. It is desirable to avoid bacterial killing methods which can alter the core.

- 15 Alternatively, complete core LPS can be isolated from the desired bacteria according to standard techniques as outlined by Hancock et al., BACTERIAL CELL SURFACE TECHNIQUES, pp. 91 (John Wiley & Sons 1988). As noted, it is preferable to include all of the core LPS,
20 without the O-polysaccharide outer LPS structures, i.e. use R-mutant bacteria expressing full LPS core.

Patient Response

- As noted, the desired patient response is cross-protective antibodies that bind to the core of rough and
25 smooth LPS of Gram-negative bacteria generally, regardless of whether their outer LPS structures are similar.

- For example, in *E. coli*, the antibodies induced by this vaccine preferably react with all common smooth
30 strain isolates, and preferably also with rough strain LPSs of all five core types (R1, R2, R3, R4, and K12). Preferably the antibodies induced by this vaccine are also reactive with different smooth and rough LPSs of *Salmonella*.

00540" 942460

- 15 -

It is possible to achieve a vigorous and effective antibody response using compositions with acceptable levels of (or no) toxicity. The vaccine stimulates the synthesis of antibodies which recognize an epitope in the core region of the LPS molecule and which are cross-protective against endotoxemia caused by at least two different Gram-negative bacterial strains having different LPS structures and in particular are cross-protective against smooth strains as well as complete core rough strains.

Typically, the vaccine will be a cocktail of the purified LPS from different strains of bacteria, preferably rough strains having a complete core, for example a mixture of LPS from K12 with LPS from R1 and R3 rough strains of *E. coli*, or with the Ra strain of *Salmonella minnesota* R60. *E. coli* R2 and R4 are less important but also candidates. Preferred cocktails (depending on the breadth of protection desired) include K12 with R1; K12 with *Pseudomonas* (e.g., *P. aeruginosa*) and *Klebsiella* (e.g., *K. aerogenes*). Since the *Bacteroides* are a particularly significant population in the gut, it may be important to protect specifically against *Bacteroides* endotoxin by including *Bacteroides* in the cocktail. e.g., together with K12 or together with K12, *Pseudomonas* and *Klebsiella*.

Alternatively, the purified LPS from one of these strains, a mixture of any combination of these strains, or a different strain of bacteria may be used in any ratio of the individual strains in the case of use of more than one LPS type.

The route of administration is preferably subcutaneous or intramuscular, although any alternative route which results in these immunogens reaching the antigen presenting cells and antibody producing cells is acceptable. Some other examples include but are not

- 16 -

limited to intravenous, intraperitoneal, and via the respiratory or gastrointestinal tract.

The dose of this composition should stimulate the host to produce increased quantities of cross-reactive
5 and cross-protective antibodies levels, consistent with avoiding toxicity, as described above.

The composition is administered before endotoxin exposure. To the extent that the vaccine works in part by stimulating the host to synthesize antibodies of the
10 IgM class, the vaccine is preferably given between 2 to 14 days prior to potential endotoxin exposure. Alternatively, additional doses of any of the possible permutations of this vaccine may allow for greater effectiveness and increases in desired antibody levels or
15 even further reduced toxicity. It is anticipated that in most vaccinees the antibody response to inner core determinants will be a secondary (i.e. memory) response as opposed to a primary (i.e. naïve) response. This is because most vaccinees will have been exposed at some
20 time in their lifetime to the LPS core epitopes, presumably from LPS that has leaked through the gut barrier into the bloodstream. In other words, an important function of our method of vaccination is to cause an increase in the serum concentration of
25 antibodies which may already be present, but at levels which do not allow for sufficient protection from a toxic exposure of LPS during periods of stress and trauma. The above in no means suggests that there are not patients who will also benefit from vaccination with this
30 invention by means of a primary (i.e. naïve) antibody response.

A vaccine with the LPS mentioned above is preferably rendered non-pyrogenic and non-toxic by incorporation of the LPS into liposomes. The liposome
35 (exclusive of the LPS component) may contain a

005240 " 042545 042546 042547 042548 042549 042550 042551 042552 042553 042554 042555 042556 042557 042558 042559 042560 042561 042562 042563 042564 042565 042566 042567 042568 042569 042570 042571 042572 042573 042574 042575 042576 042577 042578 042579 042580 042581 042582 042583 042584 042585 042586 042587 042588 042589 042590 042591 042592 042593 042594 042595 042596 042597 042598 042599 042600 042601 042602 042603 042604 042605 042606 042607 042608 042609 042610 042611 042612 042613 042614 042615 042616 042617 042618 042619 042620 042621 042622 042623 042624 042625 042626 042627 042628 042629 042630 042631 042632 042633 042634 042635 042636 042637 042638 042639 042640 042641 042642 042643 042644 042645 042646 042647 042648 042649 042650 042651 042652 042653 042654 042655 042656 042657 042658 042659 042660 042661 042662 042663 042664 042665 042666 042667 042668 042669 042670 042671 042672 042673 042674 042675 042676 042677 042678 042679 042680 042681 042682 042683 042684 042685 042686 042687 042688 042689 042690 042691 042692 042693 042694 042695 042696 042697 042698 042699 042700 042701 042702 042703 042704 042705 042706 042707 042708 042709 042710 042711 042712 042713 042714 042715 042716 042717 042718 042719 042720 042721 042722 042723 042724 042725 042726 042727 042728 042729 042730 042731 042732 042733 042734 042735 042736 042737 042738 042739 042740 042741 042742 042743 042744 042745 042746 042747 042748 042749 042750 042751 042752 042753 042754 042755 042756 042757 042758 042759 042760 042761 042762 042763 042764 042765 042766 042767 042768 042769 042770 042771 042772 042773 042774 042775 042776 042777 042778 042779 042780 042781 042782 042783 042784 042785 042786 042787 042788 042789 042790 042791 042792 042793 042794 042795 042796 042797 042798 042799 042800 042801 042802 042803 042804 042805 042806 042807 042808 042809 042810 042811 042812 042813 042814 042815 042816 042817 042818 042819 042820 042821 042822 042823 042824 042825 042826 042827 042828 042829 042830 042831 042832 042833 042834 042835 042836 042837 042838 042839 042840 042841 042842 042843 042844 042845 042846 042847 042848 042849 042850 042851 042852 042853 042854 042855 042856 042857 042858 042859 042860 042861 042862 042863 042864 042865 042866 042867 042868 042869 042870 042871 042872 042873 042874 042875 042876 042877 042878 042879 042880 042881 042882 042883 042884 042885 042886 042887 042888 042889 042890 042891 042892 042893 042894 042895 042896 042897 042898 042899 042900 042901 042902 042903 042904 042905 042906 042907 042908 042909 042910 042911 042912 042913 042914 042915 042916 042917 042918 042919 042920 042921 042922 042923 042924 042925 042926 042927 042928 042929 042930 042931 042932 042933 042934 042935 042936 042937 042938 042939 042940 042941 042942 042943 042944 042945 042946 042947 042948 042949 042950 042951 042952 042953 042954 042955 042956 042957 042958 042959 042960 042961 042962 042963 042964 042965 042966 042967 042968 042969 042970 042971 042972 042973 042974 042975 042976 042977 042978 042979 042980 042981 042982 042983 042984 042985 042986 042987 042988 042989 042990 042991 042992 042993 042994 042995 042996 042997 042998 042999 043000

- 17 -

combination of (1) a phospholipid and cholesterol or (2) a phospholipid, cholesterol and a negatively or positively charged (lipophilic) amphipathic compound. The phospholipid component may be selected from the group

5 comprising any lipid capable of forming liposomes, including, but not limited to: any phosphatidyl-choline derivative, glycerophosphatides, lysophosphatides, sphingomyelins, and mixtures thereof. The negatively charged (lipophilic) amphipathic compounds may be

10 selected from the group comprising di(alkyl)phosphates, phosphatidic acid, phosphatidylserine, phosphatidylglycerol, phosphatidylinositol, dicetyl phosphate, or any other similar negatively charged amphipathic compound that can impart a negative charge to

15 a liposome surface. When positively charged (lipophilic) amphipathic compounds are employed; they are selected from the group comprising alkyl amines, such as stearylamine and hexadecylamine. The ratio in the constituents of the liposomes (exclusive of the LPS) will

20 effect the liposomes' charge, rigidity, stability and may vary greatly while still allowing for reduced toxicity and increased immunogenicity of the LPS they contain. Polyethylene glycol lipids (PEG) may be incorporated into the liposomes, for example at approximately 10 to 20

25 mole%, in order to increase the amount of time that the liposomes remain in the systemic circulation, thus affecting their immunogenicity. Alternatively, very rigid bilayers may be made by using lipids which are gel phase at body temperature (37 degrees C), for example

30 distearoyl phosphatidylcholine or distearoyl phosphatidylserine. The type of liposomes used is preferably multilamellar liposomes (MLV) but alternatively upon sonication, or by alternative methods of manufacture, small or large unilamellar liposomes

35 (SUVs and LUVs) of varying sizes can be employed.

- 18 -

Different salt forms of LPS may alter the degree of incorporation of LPS into the liposomes, for example, the acid salt form, magnesium salt form, and calcium salt form may allow for increased incorporation due to their
5 increased hydrophobicity.

Liposomes are defined as closed vesicles, or sacs, which contain phospholipids (examples of which are lecithin and sphingomyelin) and which may contain other lipids (examples of which are cholesterol and other
10 steroids; charged lipids such as dicetyl phosphate and octadecylamine; glycolipids; fatty acids and other long-chain alkyl compounds; hydrophobic glycoproteins; and lipid soluble vitamins and lipoidal surfactant-like molecules). When shaken in the presence of an excess
15 amount of water, the lipid mixture is formed into discrete particles consisting of concentric spherical shells of lipid bilayer membranes which are referred to as multilamellar liposomes (MLV). Upon sonication, or by alternative methods of manufacture, small or large
20 unilamellar liposomes (SUV or LUV, respectively) can be formed.

Upon injection into animals and man, liposomes are taken up rapidly by cells of the reticuloendothelial system, particularly those of the liver. Because of the
25 relative impermeability of liposomes and their speedy removal from the circulatory system, substances such as lipid A and certain forms of LPS remain incorporated within the liposomes and are less likely to be exposed to cells and/or receptors through which they can exert
30 potentially toxic effects. Moreover, liposomes may allow for a prolonged effectiveness through slow biodegradation of the multilamellar membrane structure of the liposomes.

The toxicity of the lipid A component of the above mentioned complete core rough mutant strains also can be
35 reduced or eliminated by chemical detoxification as

005240" 94546" 042500

- 19 -

described in Bhattacharjee A et al., WO 95/29662. The preferred method for this detoxification maintains the LPS configuration such that it still stimulates the synthesis of antibody/ies which recognize an epitope in the core region of the LPS molecule and which is cross-protective against endotoxemia caused by at least two different Gram-negative bacterial strains having different core structures. In particular, the antibodies synthesized in response to this vaccine are cross-protective against smooth strains as well as complete core strains. The detoxified LPS may be administered in the form of purified LPS, or alternatively can be incorporated into liposomes or complexed to an acceptable carrier.

Alternatively the toxicity of the lipid A component of the above mentioned strains of bacteria can be reduced or eliminated by genetic alteration of the bacterial strains as described in Somerville JE et al, J Clin Invest 1996; 97:359-365. The resulting LPS from these cells (in the form of heat killed cells) is reduced in toxicity while still affording immunogenicity to LPS core. The preferred method for this genetic alteration maintains the LPS in a sufficient three-dimensional shape that it still acts sufficiently as an immunogen in a host to stimulate the synthesis of antibody/ies which recognize an epitope in the core region of the LPS molecule and which is cross-protective against endotoxemia caused by at least two different Gram-negative bacterial strains having different core structures. In particular, the antibodies synthesized in response to this vaccine are cross-protective against smooth strains as well as complete core rough strains. At the same time, this genetic process preferably renders the LPS non-pyrogenic and non-toxic in the warm-blooded animal. The LPS from these genetically altered bacterial

09423546-042500

- 20 -

strains are preferably administered in form of purified LPS incorporated into liposomes. LPS from these altered strains can alternatively be administered in the form of killed cells. Alternatively, the detoxified LPS may be
5 administered in the form of purified LPS, or alternatively can be complexed to an acceptable carrier.

Toxicity of any of the LPS rough antigen compositions described in this invention may also be reduced by other methods, for example, competitive
10 detoxification of lipid A by synthetic anti-endotoxin peptides. Rustici et al. Science 259:361 (1993). An alternative method of reducing toxicity is to administer the LPS antigen with or at around the same time as an anti-inflammatory agent, e.g., anti-TNF-alpha monoclonal
15 antibody. Fisher CJ et al. N Engl J Med 334:1697 (1996).

EXAMPLES

Examples herein offered to illustrate the invention are not intended to limit the scope thereof. These examples are offered to indicate experiments that may be done,
20 with no implication that all or any of the experiments have in fact been performed.

Materials for liposome preparation

Synthetic dimyristoyl phosphatidyl choline (DMPC), dimyristoyl phosphatidyl serine, and dimyristoyl
25 phosphatidyl glycerol (DMPG) were purchased from Avanti Polar Lipids. Cholesterol, 3-(N- Morpholino) propane sulfonic acid (MOPS), periodic acid, and pararosaniline based Schiff's reagent are purchased from Sigma. Sterile saline and water for irrigation are purchased from Abbott
30 labs. 3M Empore solid phase extraction discs are obtained from Fisher. Limulus amebocyte lysate (LAL)

- 21 -

standards and reagents are obtained from Associates of Cape Cod.

Materials and reagents are depyrogenated in one or more of the following procedures: 1) Heating- glassware are heated to approximately 180 degrees for no less than 16 hr; 2) Base Treatment- immersed in isopropanol/concentrated potassium hydroxide for not less than 2 hours; 3) Hydrogen Peroxide- immersed in concentrated hydrogen peroxide for not less than 1 hour at 70 degrees Celsius then rinsed with depyrogenated water; 4) Ultrafiltration- solutions are filtered through Amicon centrprep ultrafiltration membranes (3000 M.W.).

All glassware, plasticware, solutions, and buffers are free of contaminating endotoxin and verified by use of the standard LAL assay (Pyrotell and Pyrochrome from Associates of Cape Cod, Cape Cod, MA, USA).

MOPS Saline Buffer and 0.5% periodic acid solutions are stored at room temperature prior to use. Lipid stock solutions are stored at -20 degrees Celsius. LPS is stored dissolved in water for irrigation or in 0.1% TEA in glass or polystyrene containers (Evergreen) at 4 degrees Celsius. Liposome preparations are stored at 4 degrees Celsius. Pararosaniline based Schiff's reagent is stored at 4 degrees Celsius prior to use.

Methods

Lipopolysaccharide

Established strains of the following bacteria are maintained according to standard procedures: K12, R1, R2, R3, and R4 rough strains of E. coli, E. coli smooth strains O18, 06, 0157, 012, 015, and the Ra strain of Salmonella minnesota R60 can be obtained as described above. Smooth and rough LPS are purified according to the established method described in Hancock et al., cited above, pp 91-92. LPS from E. coli J5 (Rc chemotype), E. coli, S. minnesota R595 (Re chemotype), and S. minnesota

- 22 -

(wild type), and *S. typhimurium* (wild type) can be obtained from List Biological Laboratories Inc. (Campbell, Calif). Native LPS may be used as well as acid form (deionized) LPS made by electrodialyzing the native LPS using the established method described in Hancock et al. cited above at 93-95.

Incorporation of LPS into Liposomes

Liposomes are prepared by standard procedures. Multilamellar vesicles (MLV) are prepared according to the method of Dijkstra et al, J Immunol Methods 1988; 114:197-205, with some modifications, as indicated in Methods #1 and #3, below, or a novel method (method #2).

For example, in method #1, 1 ml of 5 mg/ml of native *E. coli* K12 (Ra) LPS in water was added to a 1 ml aqueous dispersion of 50 mg lipid (DMPC:DMPG:cholesterol, 4:1:4, mol/mol), i.e. a lipid:LPS ratio of 10:1 (wt/wt). The combined solution was then probe sonicated at 40-50 degrees Celsius for five 2 minute periods with 2 minute wait periods in between each sonication. The solution was then rotovapped to dryness and resuspended in a buffer consisting of 4 mM MOPS, 153 mM NaCl, pH 7.8. LPS not incorporated into the liposomes (free LPS) was removed by centrifuging the preparation 3 times at 10,000 rpm in a Komp Spin KA 21.5 rotor for 10 minutes, decanting all supernatant, and resuspending the pellet in the original volume of buffer. This procedure was repeated 3 times and reduced the concentration of unincorporated LPS significantly. This method for reducing free LPS can be used following most liposome preparation methods.

In method #2, a solution of 5 ml chloroform:methanol (2:1, v/v) was vortexed together with 2 ml of 0.1 M HCl. The lower organic phase was then allowed to separate from the upper, removed, and used to

005240-9452460

- 23 -

dissolve 5 mg of acid form LPS. 50 mg of lipid (DMPC:DMPG:cholesterol, 4:1:4, mol/mol) was then dissolved in the LPS solution. The solution of codissolved LPS and lipid was rotovapped to dryness, and resuspended as in method #1.

In method #3, briefly, a 1 ml of a lipid stock solution consisting of 4 mM dimyristoyl phosphatidyl choline:1mM dimyristoyl phosphatidyl serine: 4 mM cholesterol was rotovapped to dryness at 50 degrees Celsius. 50 μ l of a 0.1 mg/ml solution of mixed LPS consisting of equal weights of LPS from Escherichia coli strains K12, R1, R2, R3, R4 and Salmonella minnesota R60 suspended in 0.1% TEA is added with 150 μ l of water. The preparation was then vigorously vortexed and sonicated for not less than 5 minutes in a bath type sonicator with hot tap water in the bath. The preparations were then rotovapped (or lyophilized) to dryness again and resuspended in a buffer consisting of 4 mM MOPS 153 mM saline pH 7.8 with vigorous vortexing.

In some of the methods of incorporation of LPS into liposomes a single LPS type was used (e.g. 5 mg of E. coli K12 (Ra)) while in others, equal amounts of different LPSs were used (e.g. 0.83 mg of LPS from 6 complete core rough mutants).

Large unilamellar vesicles (LUV) were prepared from MLV by repeated (minimum of 15) passages through a depyrogenated pair of 100 nm polycarbonate membranes housed in an Avestin Liposofast extruder which was also depyrogenated prior to use by the hydrogen peroxide treatment above.

LPS incorporated into liposomes from method #3 was purified on a 1.1 x 28.5 cm BioGel A15M column using 4 mM MOPS/153 mM saline as the running buffer and 0.7 ml/min as the flow rate. This step maybe unnecessary since there was no difference in the lymulate ameoba lysate

005270 942546 042500

- 24 -

(LAL) activity between purified and unpurified liposomes due to the almost complete (>99.9%) incorporation of the free LPS into the liposomes.

In vitro Quantitation of Toxicity of LPS

5 Quantitation of the biological activity of the toxic lipid A component of all samples of vaccine and controls was accomplished using the standard LAL assay according to the manufacturer's instructions. (Pyrotell and Pyrochrome from Associates of Cape Cod, Cape Cod, MA, 10 USA). The rate of incorporation of free LPS into liposomes is generally reflected by a significant decrease of LAL activity following effective incorporation. Rates of incorporation of LPS into liposomes using traditional methods, including those 15 described above, usually exceed 90% and in some of the methods exceeded 99%.

Periodic Acid/Schiff's Base (PAS) Stain for LPS

Aliquots of LPS containing either MLV or LUV are diluted to 2 ml with water and extracted with 2 ml 20 toluene. After vortexing and a 5 minute 2800 rpm centrifugation in a Sorvall GLC-2 centrifuge, the upper toluene phase is removed and the aqueous phase is reextracted with 2 ml of fresh toluene. The aqueous phase and interphase are then taken, acidified with 30-50 25 μ l of concentrated hydrochloric acid and extracted with 5 ml of chloroform:methanol (2:1). The aqueous phase is reextracted once with chloroform and the combined organic phases are dried under nitrogen at 50-60 degrees Celsius. Residues are then dissolved in chloroform:methanol (2:1) 30 and spotted on an Empore C8 extraction disc alongside an LPS standard curve spotted from 50% ethanol. Discs are dried in vacuo and incubated in 0.5% periodic acid at room temperature for approximately 30 minutes. They are then removed, rinsed with distilled water, and placed in

005240" 9452460

- 25 -

capped test tubes containing pararosaniline based Schiff's reagent. The tubes are then warmed under hot tap water until color develops. The discs are then removed, rinsed again, and dried. Quantitation of the
5 resulting spots is done on an Agfa Arcus II desktop scanner in conjunction with Adobe Photoshop and NIH Image software.

Immunization and Pyrogenicity testing

The pyrogenicity and toxicity of a vaccine
10 comprised of LPS is best measured in the rabbit model of pyrogenicity established and outlined in the United States Pharmacopiae. (USP 23, <151>, 1995, Rockville, MD) In this established protocol, if an experimental substance is administered and does not cause pyrogenicity
15 in rabbits relative to control animals, that substance is defined as being non-pyrogenic and is unlikely to cause fever or toxicity in other mammals, particularly humans, following its administration. This protocol is an ideal model since rabbits and humans are similarly sensitive to
20 endotoxin.

Briefly, mature female New Zealand White rabbits between 1.8 and 3.0 kg were sham tested twice to insure their suitability for pyrogenicity testing. All testing materials were administered as specified, either
25 intravenously (IV) as a 1 ml volume or intramuscularly (IM) as a 0.6ml volume. Three rabbits are used per group as necessary for tests completed to comply with regulatory requirements. However, 2 rabbits per group were sufficient to demonstrate large differences in
30 pyrogenicity between free LPS and LPS incorporated within liposomes in examples described below. Temperatures of the rabbits were measured to insure a steady baseline and following administration of the test sample were monitored at 15 minute intervals for 3 hours. A material

005240 942546 042500

- 26 -

is considered non-pyrogenic if no rabbit shows an individual rise in temperature of >0.5 degrees C above baseline.

Measures of Efficacy of Various Immunogens

5 A well recognized test for the effectiveness of an immunogen is to administer the immunogen to a warm blooded animal, typically a rabbit or a human subject, and then withdraw blood samples periodically for the determination of antibody levels. Blood samples were
10 drawn from a marginal ear vein into a red top tube the day before testing and at different time points following intramuscular (thigh muscle) immunization. Some intramuscular immunizations were performed with the administration of the adjuvant Alum. In these cases 0.3
15 ml (equal to 1.50 mg) of Alum (Alhydrogel 0.5% diluted from stock 2%, Sergeant Co., Clifton, NJ) was mixed thoroughly with 0.3 ml of vaccine immunogen prior to administration. Blood was centrifuged, the serum removed, and stored at -80 degrees C.

20 Binding of immunized rabbit serum to LPS by ELISA

The cross-reactivity of sera from the immunized rabbits was determined by a standard method of binding of sera to purified LPS in enzyme-linked immunosorbent assay (ELISA). Sera was obtained from rabbits before and after
25 immunization with different possible immunogens. This sera was tested against numerous purified LPS in order to determine the degree of horizontal cross-reactivity and vertical cross-reactivity of the sera. The rabbit serum following the method of active immunization described in
30 this invention bound to smooth and complete core rough LPS of Escherichia coli as well as smooth and complete core rough LPS of Salmonella. It demonstrated superior binding than sera from rabbits immunized with immunogens

005240" 9452460

- 27 -

from prior art such as the extensively tested Rc J5 mutant of Escherichia coli, the Re mutant of Salmonella minnesota, and lipid A.

LPS-polymyxin complexes

5 LPS molecular weights were calculated as described previously (Scott BB et al., Serodiag Immunother Infect Dis; 4:25(1990)). Purified LPS at 0.2mM in pyrogen-free water (5ml) were mixed with polymyxin B sulphate (Sigma) at 0.4mM in pyrogen free water (5ml), and sonicated
10 together with approximately ten short (5 second) bursts of sonication. The resulting milky suspension was placed in a 2000 MWCO membrane and dialysed overnight against freshly-distilled water containing 0.05% Na azide (w/v) to remove excess uncomplexed polymyxin B. The dialysed
15 material, often presenting as a floccular precipitate, was recovered as a 10ml suspension with a presumptive LPS concentration of 0.1 mM, and stored in polypropylene Minisorb tubes (Nunc) at -40C.

LPS coating on microplates.

20 LPS-polymyxin complexes were resuspended with sonication. LPS-polymyxin complexes were diluted 1:80 in 0.05 M carbonate-bicarbonate buffer pH 9.6, containing 0.05% sodium azide, which had been freshly prepared using freshly-distilled water. The diluted complexes
25 (containing 1.25 micromolar LPS) were maintained in even distribution in coating buffer by continuous rapid stirring, and added at 100 microlitres per well to 96-well microtitre plates or 8-well microtitre strips (in 96-well frames). The microtitre plates and strips used
30 were ELISA-grade polystyrene (Greiner, medium-binding grade, flat-bottom wells): some other grades and some other manufacturers microtitre plates may be unsuitable for this assay. Plates were stacked, wrapped in plastic (Clingfilm), and incubated overnight at 37C. The plates
35 were washed as previously described using phosphate-

09423546-042500

- 28 -

buffered saline (PBS) with 0.05% (v/v) tween-20. A 5% solution of bovine serum albumin (BSA) in PBS, containing 0.05% sodium azide, was added at 120 microlitres per well. The plates were stacked, wrapped in plastic, and incubated overnight at 37C. The plates were washed as before, rinsed using freshly-distilled water, blotted by inverting on absorbent paper, and dried at 37C. The dried plates were sealed in plastic bags (one plate per bag) and stored at -40C until used.

10

LPS ELISA

Samples of test serum or plasma were diluted 1:200 in ELISA diluent [PBS / tween-20 (0.05% v/v) / polyethylene-glycol 8000 (4% w/v) / BSA (1.0% w/v) / sodium azide (0.05% w/v)], and added at 100 microlitres per well, in triplicate, to LPS-coated plates. Plates were incubated at 37C for 5 hours in a still-air (no fan) incubator, then washed (PBS / tween). Other dilutions, incubation durations, and test replication may be used, however, for any given set of experimental control and experimental groups should be subjected to identical conditions. An alkaline-phosphatase-conjugated species-specific, immunoglobulin heavy-chain-specific antibody was used to determine the amount of each immunoglobulin class bound. IgM antibodies were determined with mu-chain specific conjugates and IgG antibodies were determined with gamma-chain specific conjugates. Heavy-chain specific species specific antibodies (e.g. anti-rabbit Ig antibodies purchased from Harlan Sera-Lab (UK), were used at 1:1000 in ELISA dilution buffer. The diluted conjugates were added at 100 microlitres per well, and plates were incubated for 120 minutes at 37C. The plates were washed in PBS / tween, rinsed in distilled water, blotted, and 100 microlitres of freshly-prepared pNPP alkaline phosphatase substrate solution (Sigma N-2770) was added per well. The color was allowed

00423546-042500

094344

5 at 405 nm and 650nm (reference). Alternatively, test
results can be read as above and expressed as a
percentage of a standard on the same plate using
automated curve fitting from device-related software
(Molecular Devices Softmax). Test samples can be
10 compared to a laboratory standard immune serum from the
same species, placed as a triplicate series of 8 doubling
dilutions in ELISA diluent (standard curve) from, say,
1:50, down one column of triplicate wells on each
microplate.

15 Binding of immunized rabbit serum to LPS by Western
 Blotting

The cross-reactivity of sera from the immunized rabbits was also determined by the standard method of binding of sera to purified LPS in Western blotting.

20 Sera was obtained from rabbits before and after
immunization with different possible immunogens. This
sera was tested against numerous purified LPS in order to
determine the degree of horizontal cross-reactivity and
vertical cross-reactivity of the sera. The rabbit serum
25 following active immunization with the method of active
immunization described in this invention bound to smooth
and complete core rough LPS of Escherichia coli as well
as smooth and complete core rough LPS of Salmonella. It
demonstrated superior binding than sera from rabbits
30 immunized with immunogens from prior art such as the
extensively tested Rc J5 mutant of Escherichia coli and
is expected to demonstrate superior binding compared with
serum from rabbits immunized with purified lipid A as
well as rabbits immunized with LPS from the Re mutant of
35 Salmonella minnesota.

- 30 -

PAGE analysis was performed on 12% (w/v) acylamide gels with the buffer system of Laemmli (Nature; 227:680-85 (1990)), except SDS was omitted from the stacking and separating gel buffers. Samples of LPS (5-10 micrograms for rough LPS and 20-25 micrograms for smooth LPS, mixed with Laemmli's sample buffer) were loaded onto the gel and electrophoresed at 60 volts until the sample had entered the separating gel, and then at 150 volts until the dye front had migrated 7.5 cm through the gel. The separated LPS was stained by the modified silver stain of Hancock and Poxton (Bacterial Cell Surface Techniques, pub. Wiley, p. 281 (1988)) except that oxidation was done for 15 minutes. For immunoblotting, the LPS was transferred to nitrocellulose membrane (Schleicher and Schuell, Germany), 0.2 micrometer pore size at 10-12 volts for 16 hours at 4 degrees Celsius with the Tris, glycine, methanol buffer of Towbin et al, Proc Natl Acad Sci USA; 76:4350-54 (1979)). The transferred LPS was immunostained as described in Hancock and Poxton (Bacterial Cell Surface Techniques, pub. Wiley, p. 204-5 (1988)), except that incubation times and serum dilutions were selected to give best results, and the immunoblot was rinsed prior to developing.

The LPS content extracted from a smooth bacterium was separated by electrophoresis into bands corresponding to LPS molecules having different molecular weights, depending on the size of the O-specific side chain. These LPS molecules ranged from LPS molecules without any O-specific side chain (equivalent to the size of a complete core (Ra) rough mutant) to LPS molecules having 40 or more units in the side chain.

Protection Based on Inhibition of LPS Induced Stimulation of the LAL Assay by Serum from Vaccinated Rabbits

The limulus amebocyte lysate (LAL) assay is an established test for the biologic activity/toxicity of

- 31 -

lipid A (the toxic component of LPS). This assay quantitates the activity of a biologically active LPS, whereas in the presence of protective anti-LPS antibodies there is significant inhibition of the LAL test due to competitive binding and neutralization of the LPS. There are numerous methods for using the LAL assay to demonstrate protection from anti-LPS antibodies. LAL test kits can be purchased from manufacturers, e.g. Coatest Endotoxin from Chromogenix, Sweden. Different versions of the LAL assay can be used, e.g. gel-clot version or chromogenic version.

In an example of this method, a kinetic chromogenic LAL assay was used. In this assay, serum was obtained from a rabbit before and after vaccination with complete core LPS incorporated into liposomes. E.coli R1 LPS (1000 micrograms/ml) was diluted 1/5 into pyrogen-free water on a microplate, then five-fold diluted across the plate, allowing for a final volume of 40 ul in 5 wells (1000 ug/ml to 1.6 ug/ml). Dilutions of LPS are performed to avoid: 1) having only wells in which there is not enough LPS to cause LAL activation in the presence of serum; 2) having only wells in which there is an excessive amount of LPS. There was a dilution series for each serum or control to be tested (total 3 rows).

Row A- pyrogen-free water
row B- day-0 rabbit serum (complete core immunogen)
Row C- day-63 rabbit serum (complete core immunogen)

20 ul of water or rabbit serum was added to each well and left for 30 minutes at room temperature. 20 ul of LAL/substrate was then added using a multi-tip pipettor (start of reaction) to each well, placed immediately in reader, and read at 20sec intervals for 120 minutes. The time (seconds) from start of reaction to an optical density (OD) of 0.5 is a reflection of the degree/speed of LAL activation. In the presence of water and LPS, the

- 32 -

LAL reaction proceeded quickly and an OD of 0.5 was reached quickly. Pre-immunization serum contains some anti-LPS antibodies as well as non-specific inhibitors of LPS (e.g. lipoproteins). This serum partially
5 neutralized the LPS thus slowing down the LAL reaction and increasing the time required for the OD to reach 0.5. Post-immunization serum from the complete-core immunized rabbit resulted in a significant
10 neutralization/protection of the R1 LPS as evidenced by the marked prolongation of the time required to reach an OD of 0.5. Similar results were obtained using other types of stimulating LPSs and were consistent with the ELISA LPS binding data described earlier.

In another method using inhibition of LAL
15 activity, a known quantity of LPS is added to several dilutions of serum from both pre- and post-vaccinated subjects and the LAL activity (EU) for each is compared. Protective anti-LPS antibodies in serum, in particular the post-vaccination serum, result in lower LAL activity
20 compared with the pre-immunization value.

Cross-Protection Based on Inhibition of LPS-Induced IL-6 Secretion by Murine Peritoneal Macrophages

Several monokines including tumor necrosis factor (TNF), IL-1, and IL-6 mediate many of the
25 pathophysiologic events associated with Gram-negative endotoxemia. These monokines are secreted by monocytes and macrophages both in vitro and in vivo, in response to LPS. Serum with protective anti-LPS antibodies block the LPS induced macrophage or monocyte stimulation as shown
30 in the following assay. This type of assay can be done using established mouse cell lines (e.g. J774.2), established human cell lines (e.g. THP-1), freshly obtained mouse peritoneal cells (C3H/HeN), or freshly obtained human monocytes/macrophages. Following
35 stimulation with LPS, the assay can test for TNF or IL-6

- 33 -

levels. The amount of any type of LPS (e.g. E. coli R1) used to stimulate the cells needs to be determined in preliminary experiments. Too little LPS results in inadequate stimulation and undetectable monokine levels in the control group whereas too much LPS can overwhelm even a large amount of protective antibody. Serum with protective antibodies results in a lower monokine level (for example, the TNF level), compared with serum controls following stimulation with LPS.

10 In one example, this assay was performed as in Delahooke DM et al. Infection and Immunity, 1995, p 840-46. This assay uses a human cell line (THP1) which secretes TNF following stimulation with LPS. In this assay, the serum after vaccination with complete core
15 antigen demonstrated significant inhibition of TNF induction

In another example, mouse peritoneal cells (C3H/HeN) are obtained by peritoneal lavage with 0.34 M sucrose in distilled water. Peritoneal cells are seeded
20 at 5×10^5 cells/ml in 0.2 ml serum free medium (IMDM-ATL, Schreier and Tees, Immunological Methods, Vol. II, Acad. Press (1981) : 263) and cultured for 4 hours at 37 degrees C in the presence or absence of (1) LPS, e.g. LPS from E. coli R3 (0.05 ng/ml) or E. coli O18 (0.05 ng/ml)
25 or S. minnesota wild type smooth (0.05 ng/ml) or S. minnesota R60 (0.05 ng/ml); and (2) in the presence or absence of diluted or undiluted serum from rabbits immunized with varying immunogens, e.g. composition described in this invention or Rc J5 mutant of E. coli or
30 Re mutant of S. minnesota. The supernatants are recovered and the amount of IL-6 present in the supernatants is then measured using the IL-6 dependent hybridoma cell-line B13.29 (Aarden et al., Eur. J. Immunol. 1987, 17, 1911) as follows:

005240" 945500

- 34 -

B13.29 cells are seeded at 2.5×10^4 cells/ml in serum free medium and cultured for 72 hrs in the absence of IL-6 and in the presence or absence of culture supernatant. Aliquots of the cultures (200 μ l/well) are distributed in flat bottomed microtiter plates. IL-6 concentration in the supernatants is calculated in relation to a standard curve of IL-6. The post-immune serum should cause reduced IL-6 secretion compared to the pre-immune serum.

10 Cross-Protection from Lethal Dose of Endotoxin

Another measure of the effectiveness of this invention is its ability to confer cross-protection against LPS. A mouse lethality model is used in which mice are immunized intraperitoneally on Day 0 with either the invention, appropriate controls, or immunogens described previously such as the Rc J5 mutant LPS of Escherichia coli and the Re mutant LPS of Salmonella minnesota. A second dose of antigen is administered on Day 7 and Day 14. Between days 19 and 21 endotoxin can be administered intravenously in a 95% lethal dose of a particular LPS to groups of six female C57BL/6 mice, 6-8 weeks old. Galactosamine (D-GalN) (800 mg/kg) is administered intraperitoneally at the time of the LPS. The minimum intravenous dose of LPS required to kill approximately 95% of the animals (LD_{95}) is determined in preliminary experiments. Survival is recorded up to 24 hours. Alternative methods can be used in this protocol without substantially changing its ability to demonstrate whether immunization with a particular immunogen results in protective antibodies. For example, other strains of mice can be suitable, the galactosamine dose can be modified, and the dosing schedule of vaccination can be altered so as to administer more doses. The experiment can also be performed by isolating

005270" 9452460

- 35 -

serum from rabbits immunized with the experimental immunogen, and then administering the serum to mice prior to challenge with galactosamine and LPS. This method using passive immunization can be used to demonstrate the protective nature of serum.

Example 1

Liposomes containing *E. coli* K12 complete-core LPS were made according to method #2, above. Liposomes containing a cocktail of six complete-core LPS (*E. coli* R1-R4, K12, *S. minnesota* R60 Ra) were made according to the method described above.

Groups of three mature rabbits were immunized intramuscularly using a dose of 0.5mg of antigen with Alum (as described earlier) on days 0, 14, and 56. On days 0, 14, 21, 56, and 63, blood was withdrawn and processed as described earlier.

Using the ELISA method described earlier, rabbits immunized with K12 demonstrated increases in both IgM and IgG antibody levels to smooth and rough forms of LPS from *E. coli* and *Salmonella* bacteria.

Using the Western/immunoblot method described earlier, serum from both groups of immunized rabbits demonstrated enhanced binding to smooth and rough forms of LPS from *E. coli* and *Salmonella typhimurium*. Binding of serum from rabbits immunized to K12 alone to smooth forms of LPS from *E. coli* (serotypes 018, 012 and 015) as well as to the LPS from *Salmonella typhimurium* wild type was comparable to binding of serum from rabbits immunized with the cocktail of six complete LPS cores.

Example 2

Purified lipopolysaccharide in equivalent amounts from the following rough strains of bacteria having a complete core, R1, R2, R3, R4, and K12 strains of *E. coli* and the Ra strain of *Salmonella minnesota* R60, are tested either alone or following their incorporation into

- 36 -

liposomes as described earlier. Heat killed cells and liposomes alone are also evaluated. Compositions are made according to the materials and methods described earlier.

5 Groups

1. 100 µg of MLV (no LPS)
2. Purified LPS (3 ng total) from E. coli R1
3. purified LPS (0.3 ng total) (0.05 ng each of E. coli K12,R1,R2,R3, and R4, and S. minnesota R60)
- 10 4. purified LPS (3 ng total) (0.5 ng each of E. coli K12,R1,R2,R3, and R4, and S. minnesota R60)
5. purified LPS (30 ng total) (5 ng each of E. coli K12,R1,R2,R3, and R4, and S. minnesota R60)
6. purified LPS (300 ng total) (50 ng each of E. coli
- 15 K12,R1,R2,R3, and R4, and S. minnesota R60)
7. Cocktail of the 6 LPSS mentioned above incorporated into MLVs as 1:1000 ratio by weight (LPS:lipid) (3 ng total) (0.5 ng each of E. coli K12,R1,R2,R3, and R4, and S. minnesota R60)
- 20 8. Cocktail of the 6 LPSS mentioned above incorporated into MLVs as 1:1000 ratio by weight (LPS:lipid) (30 ng total) (5 ng each of E. coli K12,R1,R2,R3, and R4, and S. minnesota R60)
9. Cocktail of the 6 LPSS mentioned above
- 25 incorporated into MLVs as 1:1000 ratio by weight (LPS:lipid) (300 ng total) (50 ng each of E. coli K12,R1,R2,R3, and R4, and S. minnesota R60)
10. Cocktail of the 6 LPSS mentioned above incorporated into LUVs as 1:1000 ratio by weight
- 30 (LPS:lipid) (3 ng total) (0.5 ng each of E. coli K12,R1,R2,R3, and R4, and S. minnesota R60)
11. Cocktail of the 6 LPSS mentioned above incorporated into LUVs as 1:1000 ratio by weight

005210" 945460

- 37 -

(LPS:lipid) (30 ng total) (5 ng each of E. coli K12, R1, R2, R3, and R4, and S. minnesota R60)

12. Cocktail of the 6 LPSs mentioned above incorporated into LUVs as 1:1000 ratio by weight

5 (LPS:lipid) (300 ng total) (50 ng each of E. coli K12, R1, R2, R3, and R4, and S. minnesota R60)

13. Heat killed cells from E. coli R1 (amount that has same LAL activity as 3 ng of E. coli R1 LPS)

005240" 9452460
